The Role of Meteorological Parameters in COVID-19 Infection

ABSTRACT

Objective: The SARS-CoV-2 infection outbreak was given the name Coronavirus Disease 2019 (COVID-19) by the World Health Organization. Meteorological parameters are one of the most important factors affecting infectious diseases. The aim of this study is to analyze the correlation between meteorological parameters and the COVID-19 pandemic.

Methods: One hundred ninety-seven COVID-19 patients diagnosed and treated in the Turkish province of Duzce between 29.03.2020 and 04.05.2020 were included in this study.

Results: We found the relationship between air quality parameters and COVID-19 case numbers revealed significant negative correlation between positive patient number and air temperature, relative humidity, and NO2, and significant positive correlation with air pressure, but no correlation with PM10, PM2.5, SO2, NO, or CO.

Conclusions: Our findings are important as a preliminary study, since interactions between air pollutants and meteorological factors may be involved in the transmission and pathogenesis of COVID-19, and large-scale studies should now be designed for a better understanding of these interactions.

COVID-19 Enfeksiyonunda Meteorolojik Parametrelerin Rolü

ÖZET

Gereç ve Yöntem: Türkiye Düzce ilinde 29.03.2020 ve 04.05.2020 tarihleri arasında tanı ve tedavi edilen 197 COVID-19 hastası çalışmaya alınan hastaların analizi yapılarak çalışıma alınması sağlanmıştır.

Bulgular: Hava kalitesi parametreleri ile COVID-19 olgu sayıları arasındaki ilişkinin, pozitif hava sıcaklığı ile hava sıcaklığı, bağıt nem ve NO2 arasında anlamlı pozitif korelasyon olduğu ve hava basınç ile anlamlı pozitif korelasyon olduğu, ancak PM10, PM2.5, SO2, NO ve CO ile korelasyon olmadığı saptandı.

Sonuç: Bulgularımız bir ön çalışma olarak önemlidir, çünkü hava kirleticileri ile meteorolojik faktörler arasındaki etkileşimler COVID-19’un bulasması ve patogenezinde rol oynayabilir ve bu etkileşimlerin daha iyi anlaşılmasını için büyük ölçekli çalışmalar tasarlanmalıdır.

INTRODUCTION
The SARS-CoV-2 infection outbreak was given the name Coronavirus Disease 2019 (COVID-19) by the World Health Organization (WHO). COVID-19 then spread rapidly to many countries, and the WHO officially declared it a pandemic on 11 March, 2020 (1).

Viruses do not replicate outside the living cell, but the virus can survive on environmental surfaces it has contaminated, that survival being significantly affected by temperature and moisture (2).

Meteorological parameters are one of the most important factors affecting infectious diseases. Previous studies have suggested that environmental air pollutants make humans more susceptible to pathogens by carrying micro-organisms and are risk factor for respiratory tract diseases by affecting the body’s immunity (3-5).

Various studies have been performed to investigate the factors affecting SARS-CoV-2 transmission in order to control the spread of COVID-19 (6). Several factors affect the transmission, such as the incubation period, the length of infectiousness, the virus load, the incidence and infectiousness of asymptomatic cases, transmission pathways other than droplets, and the length at which the agent can maintain infectivity in external environments (7). Air quality parameters may therefore play a role in the transmission and infectivity of the virus.

Meteorological conditions have been proposed as important factor in predicting epidemic trends, in addition to population mobility and human-to-human contact. Meteorological factors, such as humidity, visibility, and wind speed, can affect droplet stability in the environment, or affect the survival of viruses in the same way as air temperature, thus impacting on epidemic transmission. Air temperature and absolute humidity have been reported to significantly affect the transmission of COVID-19 (8).

Information concerning the survival of SARS coronavirus at different temperature and humidity conditions is of great importance to understanding the transmission of the virus. In addition to human-to-human transmission, both epidemiological and laboratory studies have shown that environmental temperature is an important factor in the transmission and survival of coronaviruses (9,10). The aim of this study is to analyze the correlation between meteorological parameters and the COVID-19 pandemic.

MATERIAL AND METHODS
Study Population: One hundred ninety-seven COVID-19 patients diagnosed and treated in the Turkish province of Duzce between 29.03.2020 and 04.05.2020 were included in this study.

Data Collection: The air monitoring measurement parameters published by the National Air Quality Network [PM10 (particulate matter less than 10 μm), PM2.5 (particulate matter less than 2.5 μm), SO2 (sulfur dioxide), NO2 (nitrogen dioxide), NO (nitrogen oxide), CO (carbon monoxide), air temperature, air pressure, relative humidity] were obtained from the relevant web site (http://laboratory.cevre.gov.tr/Default.ltr.aspx).

The study was conducted in full accordance with the local Good Clinical Practice (GCP) guideline and current legislation, while permission for the use of patient data for publication purposes was obtained from Düzce University Faculty of Medicine Ethics Committee.

Polymerase Chain Reaction (PCR)
Method: Combined nasopharyngeal-oropharyngeal swab, sputum or tracheal aspirate samples were collected from suspected cases of COVID-19. These were then sent to the laboratory under appropriate conditions in viral transport medium, where they were processed in the biosafety cabinet. Nucleic acid extractions were performed manually using Bio-speedy viral nucleic acid extraction buffer (Bioeksen R&D Technologies, Turkey). PCR testing was then performed using a SARS-CoV-2 (2019-nCoV) RT-qPCR detection kit (Bioeksen R&D Technologies, Turkey) and Montania® Real-Time PCR instruments (Anatolia Geneworks, Turkey). PCR test results were evaluated and reported by the laboratory manager.

Statistical Analysis: Statistical analysis was performed on SPSS-21 software. Descriptive statistics were calculated as frequency and mean, median, and standard deviation values. Pearson’s correlation analysis was applied to determine correlations between patient numbers at the beginning of each week over the five-week study period and mean air pollution, air temperature, relative humidity, and air pressure values. p values <0.05 were regarded as statistically significant.

RESULTS
Women constituted 51.8% (n: 102) of the 197 COVID-positive patients, and men 48.2% (n:95). Mean ages were 44.8 ± 17.8 (min:1, max:88, median 43) for women and 44.8 ± 17.7 (min:2, max: 96, median 43) for men (p=0.990). Five-week mean air parameter and pollution values are shown in Table 1.)

PM_{10}: particulate matter less than 10 μm, PM_{2.5}: particulate matter less than 2.5 μm, SO₂: Sulfur dioxide, NO: Nitrogen oxide, NO₂: Nitrogen dioxide, CO: Carbon Monoxide

Significant negative correlation was found between positive patient number and air temperature (r= -.247, p= 0.001), relative humidity (r= -.358, p<0.001) and NO₂ (r= -.225, p= 0.002) (Figures 1-3). Significant positive correlation was determined between positive patient number and air pressure (r= .444, p<0.001) (Figure 4). No correlation was determined between patient numbers by weeks and PM10, PM2.5, SO₂, NO, or CO. (p and r values r=.136 p=.076, r=.047 p=.572, r=-.133 p=.068, r= -.044 p=.549, and r=.040 p=.584, respectively).

DISCUSSION

This study investigating the relationship between air quality parameters and COVID-19 case numbers revealed significant negative correlation between positive patient number and air temperature, relative humidity, and NO\(_2\), and significant positive correlation with air pressure, but no correlation with PM\(_{10}\), PM\(_{2.5}\), SO\(_2\), NO, or CO.

It is very important to examine the effect of meteorological parameters in outbreaks involving human-to-human transmission. However, the results of studies performed in the field of the COVID-19 pandemic are discrepant. Studies of parameters associated with air pollution have generally involved the effect on COVID-19 infection mortality (11-13). However, mortality outcomes were not evaluated in the present study. In their study of the effect of air pollution of COVID-19 mortality, Xiao Wu et al. (12) reported that a small increase in long-term exposure to PM\(_{2.5}\) led to a large increase in the COVID-19 death rate.

Zhu et al. (6) investigated the association between air pollutants and COVID-19 by examining data for 120 cities, and reported significantly positive correlations between PM\(_{2.5}\), PM\(_{10}\), CO, NO\(_2\) and O\(_3\) and COVID-19 confirmed...
cases, while SO\textsubscript{2} exhibited negative correlation with the number of daily confirmed cases. No significant association between PM\textsubscript{10}, PM\textsubscript{2.5}, SO\textsubscript{2}, NO, and CO and case numbers was found in the present study. This may be due to our low case number and to our cases being included only in the Spring, and this is also a limitation of this study.

One study of case numbers and temperature in China reported that every 1 °C increase at a mean temperature of <3 °C led to an increase in case numbers, but that no such relationship was found when the mean temperature exceeded 3 °C (10). Since the increase in case numbers in China was observed in Winter, the inconsistency with our study results is an expected finding. Temperature values in Turkey in March and April were at higher levels.

Chan et al. (2) examined the stability of the SARS CoV virus at different temperatures and relative humidities and reported better stability in a low temperature and low humidity environment.

Oliveiros et al. (14) examined temperature, humidity, rainfall, and wind speed in terms of modulation of the doubling of COVID-19 cases. They reported that the time to doubling was inversely proportional with temperature and humidity. They calculated that these variables explained 18% of the change in the disease doubling time, the remaining 82% possibly being associated with limitation precautions, general health policies, population density, transport, and cultural factors.

One study examining the relationship between weather and COVID-19 in terms of nine cities in Turkey considered the five main factors of temperature, dew point, humidity, wind speed, and population. Similarly to the present study, those authors found a negative correlation between case numbers and temperature, with case numbers rising as temperature decreased (15).

Biqing Chen et al. (16) examined the effect of four meteorological parameters (air temperature, relative humidity, wind speed, and visibility) on COVID-19 infection and reported that the values for the previous 14 days were correlated with case numbers. However, they did not think that changes in a single weather factor such as temperature or humidity could be well linked to case numbers. Based on their study finding, the authors stated that governments could employ these meteorological factors in outbreak control.

The principal limitation of this study is that exposure to air pollution relied on estimation. Home specific exposure assessments could not be performed since exact addresses were unavailable. The monitoring was also limited by the number of observations taken by the National Air Quality Monitoring Network stations.

Despite these limitations, our findings are important as a preliminary study, since interactions between air pollutants and meteorological factors may be involved in the transmission and pathogenesis of COVID-19, and large-scale studies should now be designed for a better understanding of these interactions.

Conflict of Interest: Authors declared no conflict of interest.
